Organic Microbiological Studies: Effects of Organic Dyes (Gentian Violet or Methylene Blue) On Laser Lethal photosensitization of Fungus Aspergillus flavus Treated with Boric Acid

Shakir M. Saied
Dept. of Pharmacy, Institute of Technical Mosul

Abstract
Organic Dyes (Gentian Violet or Methylene Blue) had increased the lethal photosensitization of Aspergillus flavus, when were treated with boric acid of different concentrations (1% and 2%) and exposed to He-Ne laser light with absorbed doses of 1.06 and 2.12 joules/cm² respectively and survivors enumerated.

The inhibition of fungus growth was 92.2 and 96.6 % (Percentage differences from control PDC) for the coloring by Gentian Violet and 84.4 and 87.7% for Methylene Blue.

Introduction:
Aspergillus species are saprophytic fungi found in soil, water and decaying organic matter [1]. Of the 200 species in the genus only a few can cause disease and Aspergillus flavus is one of them. In the normal host, Aspergillus species can cause a wide spectrum of diseases ranging from allergic manifestations, corneal, otomycotic, nasoorbital infections and superficial infections to a life-threatening invasive disease known as invasive Aspergillosis [1-2]. Initiation of infection begins with the inhalation of conidia, the infectious particles, which adhere to and germinate in the lung tissue [3]. Hyphal invasion of the lung epithelium is followed by...
dissemination to other organs risk factors for invasive *Aspergillosis* is prolonged neutropenia and/or long-term administration of high dose corticosteroids \[3\].

Although *Aspergillus* fumigatus is the most common cause of *Aspergillosis*, but *A. flavus*, and several other species can also cause diseases. *Aspergillus* is a mold with septate hyphae about 2 - 4 um in diameter. The fungus can be identified by its gross and microscopic appearance in culture \[4\].

The extremely effective of boric acid on the growth of some fungi or their aflatoxin, and the lethal photosensitization of these fungi at exposure to He/Ne laser light or Gallium Aluminium Arsenide laser irradiations with different dyes (toluidine blue or methylene blue) was studied by many investigators \[5-9\].

As part of continuous program directed toward the studying of the biological effects of some organic and inorganic compounds \[6\], it was become of interest to investigate a comparative study between the effects of this acid in different concentrations (1% and 2%), and the lethal photosensitization toward He-Ne laser light after colored with gentian violet or methylene blue.

**Materials and methods test organism**

*Aspergillus flavus*, a fungus previously isolated from corns was used in this work.

**Inoculums preparation** \[9\]

Sabaurauds Agar medium (SAM) was used, with the following composition (g/l): Glucose, 10; Agar, 10, Pepton10 and distilled water, 1000ml. The pH value of the medium was adjusted at 5.6 then autoclaving at 1.5 atm. for 15 minutes. (SAM) medium was also used for subculturing of the test organism as well as for preparation of fungal inoculum. This was prepared in the form of fungal culture discs each of 7mm diameter using 8 days old culture. (SAM) medium was also used as control medium for measuring the toxicity of boric acid on fungal growth.

**Experimental media**

This was prepared using (SAM) medium. It was supplied singly by different concentrations of boric acid of 1% and 2%. The days (gentian violet and methylene blue) was supplied as 0.0001%.

**Expressions of results**

Fungal growth was determined by measuring the diameter of colony radial growth in mm. Data were recorded in triplicates after 8days of incubation at 28°C, and 5-10mins laser irradiations of the coloring samples. Results were expressed as percentage difference from control (% PDC).
Laser used
Laser He-Ne of wave length 632.8 nm and power output of 0.001 watt, irradiations techniques was provided in Laser Laboratory, Department of Physics, College of Education, Mosul University.

Results and discussions

Organic dyes were used very extensively as anti-infective agents before the discovery of the sulfonamides and the antibiotics, and few cationic dyes still find limited use as anti-infective [10]. These include the triphenyl methane dyes gentian violet and the thiazine dye methylene blue. Cationic dyes were active against Gram-positive bacteria and generally resistant. The difference in susceptibility was probably related to the cellular characteristics that underlined the Gram stain [10].

The dehydration power effects of boric acid on the fungal biochemistry was clearly associated with damage of the cell membrane with the loss of essential cellular components such as potassium ions and amino acids, and these effects are increased by the laser light irradiation [11-12].

Stean and Stearn indicated that the behavior of bacteria toward dyes could be explained and largely determined by its protein [13]. This behavior is increased when these dyes irradiated by laser. The use of gentian violet or methylene blue was based on the ability of these organic dyes to absorb the energy of a source and then irradiates the energy as laser irradiation [8].

Results presented in Tables (1) show that the coloring by organic dye Gentian Violet increases the lethal photosensitization of Aspergillus.
Organic Microbiological Studies: Effects of Organic.....

flavus, i.e. increases the % inhibition of fungus growth (Percentage differences from control) from 33.1 and 44.6 (of the two concentrations of boric acid) to 92.2 and 96.6 when irradiation with absorbed dose 1.06 joules/cm², and from 33.1 and 44.6 to 92.2 and 96.6 when irradiation with absorbed dose 2.12 joules/cm². While results presented in Tables (2) show that the coloring by organic dye Methylene Blue increases this % inhibition from 33.1 and 44.6 to 92.2 and 96.6 when irradiation with absorbed dose 1.06 joules/cm², and from 33.1 and 44.6 to 92.2 and 96.6 when irradiation with absorbed dose 2.12 joules/cm². The inhibition by boric acid without irradiation of growth in our early work was from 33.1 and 44.6%.

What was made these two dyes to be so suitable as laser absorbance? In the first place the C = N and the (CH₃)₂N- moieties were produced extensive conjugated system. The more extensive the molecular conjugation, the smaller the energy gap between the highest filled π orbital and the lowest empty π* orbital, then even range may be sufficient to excite the molecule. This was increased the lethal photosensitization of the culture of Aspergillus flavus.

Conclusion

Using organic dyes (Gentian Violet or Methylene Blue) of violet pigment enables a large amount of He-Ne laser light energy to focus into a small area, thereby creating a much greater photochemical UV cataract reaction than ordinary light, producing irradiation absorbed dose of about 1.06 and 2.12 joules/cm² for 5 and 10 minutes respectively, and this doses increase the thermal damage accompanied with the killing effects of inorganic molecules (boric acid), this incubation of the photosensitizes with the yeast was necessary to render it susceptible to killing by laser light.

Acknowledgment

I thank Dr. Abdulla, A.I.; Asst. professor of Laser Physics, department of physics, College of Education, Mosul University, for providing the laser irradiations techniques.
